15.3 Final Test Matrix Summary 15

15.4 Final Status 16

1. Executive Summary and Verdict

Phase 7 audited the complete Praveen Garments billing, POS and inventory application as if delivering it to a paying garment-store client: reproduce and fix every reported runtime error, sweep for placeholders, inventory every route, re-run the full database regression, and document everything honestly. The two bugs reported from the screenshots — the Purchase Invoice SelectItem crash and the Expenses "Something went wrong" state — were reproduced in a component harness, root-caused to the same Radix UI limitation in three dialogs, fixed without any error suppression, and re-verified. The fresh regression re-run of the full migration chain 0001–0014 produced 353 of 353 green checks, identical to the Phase 6 baseline, proving the fixes introduced no database regressions.

PRODUCTION
N READY

Phase 7 verdict — with the
operational checklist in Chapter 15
completed by the owner

Three honest limitations frame this verdict, unchanged in kind from Phase 6 and stated plainly: physical hardware (scanner, label printer, mobile camera) was not physically tested and is documented as software-verified only; the screenshot ZIP referenced in the audit request never reached the workspace, so that part is marked **BLOCKED**; and the rotated Supabase service key prevented authenticated browser re-testing and cloud test-user creation this session, so the two fixed dialogs need a 30-second visual re-check from the owner — the fix itself is verified at component level, by type-checking, linting, a clean production build and the hot-reloaded dev server.

2. Scope, Evidence Base and Method

2.1 What Was Tested This Session

Evidence stream	Scope	Result
Bug reproduction harness (jsdom + React 19 + Radix)	Exact user-level dialogs from the two reported bugs + mechanism proof	3/3 reproduced pre-fix; 6/6 verified post-fix
Full migration regression (local embedded PostgreSQL 18)	Chain 0001-0014 applied fresh; audit suites 1-3, 0014 suite, 0011/0012/0013 regressions	353/353 passed, 0 failed
Performance suite	50,000 sales / 150,000 items / 60,000 payments / 4,000 variants seeded locally	All 11 report queries 1.9-63.8 ms

Evidence stream	Scope	Result
Placeholder sweep	coming soon / TODO / mock / dummy / fake / hardcoded / sample / temporary across src/	Zero stub code; one dead shared component; one by-design read-only roles note
Route inventory	Every page.tsx and API route.ts in the app router tree	27 page routes + 41 API routes mapped
Static quality gates	TypeScript, ESLint on changed files, production build, dev-server hot reload	0 type errors; lint clean; build compiled in 25.9 s
Browser smoke (unauthenticated)	Login page render, console and page errors	0 console errors, 0 page errors

Table 2-1 — Phase 7 evidence streams and outcomes.

2.2 What Was NOT Tested This Session (Honest Register)

Item	Status	Reason and handling
Screenshot ZIP analysis (Part 1)	BLOCKED	The attached ZIP never reached the workspace upload directory (recurring infrastructure issue); the two bugs named in text were still fully investigated and fixed. Re-share to close this item.
Authenticated browser E2E re-run	NOT TESTED this session	Supabase service key was rotated server-side and now returns 401, so no cloud test user could be created or promoted. Phase 6 browser evidence (32 routes, 0 errors) stands; owner performs a 30-second visual re-check of the two fixed dialogs.
Physical scanner / label printer / mobile camera	NOT TESTED	No physical devices attached to the audit environment; classified software-verified in the User Guide hardware chapter.
1 crore-row load	NOT TESTED at that volume	Architecturally assessed at 50k-scale plus index/query-plan review (Chapter 11); no claim of a 1-crore test is made anywhere.

Table 2-2 — Honest not-tested register for this session.

Method note: the regression harness is a local Supabase-compatible PostgreSQL that applies the exact migration files the cloud runs, with the anon, authenticated and service_role roles and an auth.uid() stub faithful to PostgREST. Suites were executed once each in the canonical Phase 6 order on a freshly reset chain — the same discipline that produced the original 353-check baseline.

3. Screenshot ZIP Audit

Part 1 of the Phase 7 brief asks for a full analysis of an attached ZIP of screenshots. The upload directory was checked repeatedly during the session and was empty each time: the file transfer never arrived in the workspace. No screenshot was inspected, and no screenshot-derived finding is claimed. This item is BLOCKED, not passed.

The brief also named two concrete bugs in text — the Purchase Invoice SelectItem error and the Expenses "Something went wrong" state — and both were treated as first-class audit targets independently of the missing images. They were reproduced at component level with the exact production components, root-caused, fixed, and re-verified; Chapter 4 carries the full evidence. When the ZIP is re-shared, Part 1 should be re-run against this report's bug register to confirm nothing else visible in the screenshots remains unfixed.

4. Bug Findings and Fixes

4.1 Root Cause — One Bug, Three Places

Radix UI Select forbids an empty string as a SelectItem value: the component body throws "A Select.Item must have a value prop that is not an empty string" whenever such an item mounts — unconditionally, in development and production builds. Worse, Radix 2.2 mounts dropdown children into a detached document fragment even while the dropdown is closed, so the throw fires as soon as the dialog renders, not only when the dropdown is opened. React catches the render error in the page-level error boundary, which replaces the page with "Something went wrong" — the exact state seen in the Expenses workflow. The codebase had three such items, all representing an optional "none" choice.

Bug ID	Location	Symptom	Severity	Status
B-01	purchases/invoice-form-dialog.tsx — "No order (direct)"	Purchase Invoice dialog crashes the page on open (reported via screenshot text)	P0	FIXED + RE-TESTED
B-02	expenses/expense-form-dialog.tsx — "Whole business"	Expenses Record Expense dialog shows "Something went wrong" (reported)	P0	FIXED + RE-TESTED
B-03	inventory/locations-tab.tsx — "No branch"	Add/Edit Location dialog would crash the same way (found proactively, same class)	P1	FIXED + RE-TESTED

Table 4-1 — The SelectItem empty-value bug register.

4.2 The Fix — Root Cause, Not Suppression

Each optional "none" choice now uses a non-empty sentinel value ("__none__") for the item, while the Select maps the sentinel back to the empty string (or null) in its change handler, preserving the original business meaning: no order linked, whole business expense, no branch attached. No error was suppressed, no component removed, no fallback faked, no TypeScript or ESLint rule disabled. The Expenses investigation also verified the data path independently — every RPC the expenses screens call (expenses_page, get_pos_config, create_expense, approve_expense, cancel_expense) exists in deployed migrations — so the crash was never a data-layer failure.

4.3 Reproduce and Re-Test Evidence

Check	Pre-fix	Post-fix
A. Minimal Select with value="" item (mechanism proof)	CRASHED as expected — boundary caught the exact Radix throw	Pattern eliminated from src/ (grep zero) — mechanism stands as documented
B. ExpenseFormDialog renders with Branch dropdown	CRASHED at dialog mount — "Something went wrong" reproduced	No crash; dialog renders; zero errors captured
C. InvoiceFormDialog renders with Link purchase order dropdown	CRASHED at dialog mount	No crash; dialog renders; zero errors captured
D. Sentinel wiring in all three fixed files	n/a	no empty SelectItem, sentinel declared, item wired, mapped to '/null, value fallback — 3/3 files PASS

Table 4-2 — Harness results (scripts/p7-selectitem-repro.tsx, modes repro and verify).

Reproduction harness, kept in the repo

The jsdom + React 19 harness drives the real production dialog components inside a real error boundary, so the crash is caught exactly the way the app catches it. Pre-fix output (3/3 REPRODUCED) and post-fix output (6/6 VERIFIED) are saved as evidence files alongside the script; running the repro mode against the fixed code now fails to reproduce the crash — a negative control proving the fix changed real behaviour.

5. Route and Feature Inventory

5.1 Page Routes (27)

Route group	Routes	Module
Auth	/login, /forgot-password, /reset-password, / (redirect)	Authentication
Shell	/dashboard	Dashboard
POS	/pos	Billing counter
Sales	/sales, /sales/[id], /sales/[id]/invoice	Bill history and invoices
Payments	/payments	All money movements
Products	/products, /products/new, /products/[id], /products/[id]/edit, /products/attributes	Catalogue
Inventory	/inventory (tabs: current, history, locations)	Stock
Labels	/labels	Barcode/QR label printing
Purchases	/purchases	POs, supplier invoices, returns
Customers / Suppliers	/customers, /customers/[id], /suppliers, /suppliers/[id]	Accounts
Expenses	/expenses	Shop spending
Reports	/reports, /reports/[report] (17 reports)	Analytics
Settings / Users	/settings, /users	Administration

Table 5-1 — All 27 page routes in the app router tree.

5.2 API Routes (41)

Forty-one server routes back the pages: 23 under /api/admin (catalogue, variants, stock engine operations, locations, users, labels), and 18 business routes (POS checkout, hold/resume/discard held bills, customers and payments, suppliers and payments, purchase orders, purchase invoices, purchase returns, expenses with attachments, expense categories, sales cancel/return/exchange, plus /api/health). Every route is session-guarded by middleware, permission-checked server-side, and audited where sensitive. The Phase 6 browser matrix verified all 27 pages render with zero console and page errors, and the route inventory re-taken this session is unchanged except for the three fixed dialogs — no route was added or removed in Phase 7, which confirms the fix touched behaviour, not surface.

5.3 Feature Classification

Feature area	Classification	Notes
Catalogue + variants + identifiers	IMPLEMENTED	SKU case-insensitive unique, EAN-13 checksum, partial-unique barcode/QR
Stock engine + ledger	IMPLEMENTED	Atomic adjustments, transfer pairs, append-only, reason-required
POS + checkout + held bills	IMPLEMENTED	Exact-match auto-add, atomic checkout, idempotent button
Payments and accounts	IMPLEMENTED	Split, credit, FIFO allocation, statements with till payments credited
Purchases + returns + exchanges	IMPLEMENTED	Partial receiving caps, return caps, exchange difference handling
Expenses + approvals + attachments	IMPLEMENTED	Pending-approve flow, private bucket, dual validation
Reports + dashboard + exports	IMPLEMENTED	17 RPC reports, CSV export capped at 5,000 rows
Roles matrix editing in UI	PARTIAL (by design)	Read-only matrix; enforcement is database-side; labelled honestly in the UI
Module "coming soon" placeholders	NOT PRESENT	Zero routes use the placeholder component; all modules are real
Excel/CSV product import	NOT IMPLEMENTED	Documented as absent — no fake import exists anywhere
Direct thermal/ESC-POS printing	NOT IMPLEMENTED	Browser printing only; classified honestly
Cash drawer integration	NOT IMPLEMENTED	Manual key operation; documented

Table 5-2 — Feature classification against the brief's five statuses.

6. Regression Audit — 353 Checks Re-Run

6.1 Fresh Chain Application

The local harness dropped public, auth and storage schemas, re-created the Supabase-compatible stub environment (anon / authenticated / service_role roles, auth.users with the PostgREST-faithful auth.uid()), and applied all fourteen migrations in order 0001 to 0014. Every file applied cleanly, matching the cloud deployment state the owner confirmed after running 0014.

6.2 Suite Results

Suite	Covers	Result
audit1 (Phase 6 §1-16)	Users, catalogue, identifiers, scanner chain, opening stock, adjustments, transfers, concurrency (8-way last-unit race), POS checkout, double-click idempotency	73 / 73
audit2 (Phase 6 §17-31)	Payments matrix, split, credit, FIFO allocation, statements with till payments, purchase receiving caps, returns, damaged returns, exchanges, historical prices, EOD reconciliation	52 / 52
audit3 (Phase 6 §32-55)	RLS matrix incl. ghost users, report permission gates, dashboard scoping, ledger integrity, orphans, 1-crore architecture paths, session behaviour	48 / 48
0014 exchange-cash report suite	Exchange collections in payment_report, cash exchange in cash_report, permission gates	12 / 12
0011 statement regression	Till payments credited, mirrors excluded, opening balance across boundaries	27 / 27
0012 reporting regression	All 17 reports vs independent recomputation, grants, idempotent re-apply	116 / 116
0013 sales-report regression	p_payment_status filter, gate, no overload conflicts	25 / 25

Table 6-1 — Regression results on the fresh chain: 353 passed, 0 failed.

353 / 353

checks green — identical to the Phase 6 baseline; the Phase 7 fixes introduced zero regressions

6.3 Performance Re-Run

The performance suite re-seeded 50,000 sales, 150,000 sale items, 60,000 payments and 4,000 variants, then ran EXPLAIN ANALYZE on the eleven heaviest report paths. Results: sales_report 13-19 ms, product_sales 50 ms, payment_report 28 ms, gst_report 14 ms, dashboard_summary 43 ms, profit 29 ms, stock_valuation 2 ms, stock_performance 64 ms, customer_report 2 ms, audit_page 6 ms — with zero sequential scans on the date-windowed paths. The numbers sit inside the Phase 6 envelope (2-75 ms), so the 0012 report indexes remain effective at this scale.

7. Stub-Code Sweep and Quality Gates

The sweep searched all TypeScript and TSX sources for the brief's full keyword list — coming soon, later phase, placeholder, TODO, mock, dummy, fake, hardcoded, test data, development-only, temporary, sample data, workaround. Every hit was inspected. The input placeholder= attributes are ordinary HTML input hints, not stubs. The comments that mention "hardcoded" all assert the opposite — that values are database-driven. Zero TODO, FIXME, mock or dummy implementations exist in src/, and no unfinished functionality is exposed to the client.

- module-coming-soon.tsx: a shared Phase 1 component now referenced by ZERO routes — dead code, harmless, candidate for future cleanup (P3).
- Roles tab: reads "Granular per-role editing arrives in a later phase" — an honest, disclosed design note (matrix is read-only; the database enforces permissions) — classified PARTIAL by design, not a hidden stub.
- No console suppression, no disabled TypeScript/ESLint rules, no hardcoded business values: the Phase 1 discipline held through all seven phases.

Zero-error gates

TypeScript: 0 errors in src/ (pre-existing errors in legacy scripts/ and the pgtest harness are documented and predate Phase 5). ESLint: clean on all three fixed files. Production build: compiled successfully in 25.9 s with all 9 static pages generated. Dev server hot-reloaded the fixes and continued serving 200 responses.

8. Business Workflow Audits

8.1 POS, Checkout and Payments

The billing chain was re-verified end to end at database level: scan resolves to the exact variant (barcode 2900000000018 to AUD-SHIRT-BLU-M; QR AUDQRBLKM1 to AUD-SHIRT-BLK-M), the cart's repeated scans produce one sale with the summed quantity, checkout writes sale, items, payments and movements in one transaction, and the last-unit race lets exactly one of two concurrent sales succeed while the other fails cleanly with INSUFFICIENT_STOCK. Cash change, split payments and credit dues re-verified against the payment rows; customer statements close on the same due figures the account pages show.

8.2 Purchases, Returns, Exchanges, Expenses

Partial receiving still caps at pending quantity (ordered 100, received 60 means stock +60, never +100); purchase returns cannot exceed received quantities and reduce the payable correctly; sales returns net the stock exactly (sell 3, return 1, net -2) with damaged returns excluded from sellable stock; exchanges move both sides of stock and settle the price difference through real payments, which the 0014-updated payment

and cash reports now include. Expenses keep their pending-approve flow with server-side attachment validation, and the Phase 7 fix removed the crash that prevented reaching the branch dropdown at all.

8.3 Store-Day Simulation and Interlink Test

The Phase 6 full shop-day script — morning stock, purchase receiving, four customers including a double-scan, discount, split payment, credit sale, return with refund, and an exchange, plus supplier payment, customer payment and an expense — remains green inside the regression suites, and the closing reconciliation matched sales, payment split, refunds, expenses, stock, dues and payables across dashboard, reports and ledger. The product-to-report interlink chain (product to variant to identifier to stock to sale to invoice to customer to return to report) was exercised as one continuous sequence with no orphan records anywhere in the chain.

9. Data Integrity and Financial Reconciliation

Integrity check	Method	Result
Stock balance = sum of movements	Per variant+location re-summation across the seeded ledger	PASS — exact equality
Ledger append-only	Direct UPDATE/DELETE attempts as admin	PASS — refused by guard triggers
Orphan records	Sales/items/payments/moves without parents; customers without users	PASS — none
Duplicate invoices / payments / movements	Number uniqueness + document reference scan	PASS — none
Negative stock	Full-ledger scan for balance < 0 with negative stock off	PASS — none
Paid/due invariant	Payments never exceed bill total; dues never negative	PASS
Payables	Supplier payables = unpaid invoice remainder	PASS
Customer dues	Statement closing balance vs account page on every test account	PASS — to the rupee
Financial EOD	Sales + refunds + expenses + drawer split vs reports	PASS — reconciled

Table 9-1 — Data-integrity and financial-reconciliation results (from the re-run suites).

No unexplained difference exists anywhere in the re-run. Where the ledger design intentionally forbids deletion (users with movements, variants with history), the interface offers deactivation and the audit trail records the action, which is the correct garment-retail behaviour rather than a defect.

10. Security and RLS Audit

Row-level security was re-attacked from the suites: anonymous reads of business tables return zero rows; authenticated users of the wrong role receive permission denials from the RPCs (ACL before RLS — defence in depth); direct writes to stock balances and the movement ledger are refused for every client role, with balance changes possible only inside the engine’s security-definer functions; ghost users (auth rows without profiles) are rejected; dashboard and report RPCs are section-scoped per role. The app-side rules were also re-verified: service-role key never shipped to the browser (the client bundle uses the publishable key only), middleware returns 401 JSON for unauthenticated API calls, and public sign-up is not offered in the interface.

One operational security item — the rotated service key

The stored service key began returning 401 during Phase 6 recovery (the key was rotated on the Supabase side). Browser flows are unaffected; only server-side user management and cloud test-user creation need the new key pasted into .env.local. This is on the owner checklist in Chapter 15 and does not affect any in-app permission behaviour.

11. Performance and Large-Dataset Readiness

The brief targets eventual 1-crore-plus record volumes. No claim of testing at that volume is made. The honest classification is ARCHITECTURALLY READY, based on: index-backed identifier lookups (the scanner path uses the barcode and QR partial-unique indexes), DB-side pagination on every list (LIMIT/OFFSET or keyset cursors — no page fetches the full table), trigram search indexes on product names, all seventeen reports computed inside the database with the 0012 index set, and the browser never receives unbounded result sets (CSV export is capped at 5,000 rows precisely to protect the client).

Query path	Measured at 50k sales / 150k items	Scaling property
sales_report (date window)	13-19 ms	Index range scan on sale date
dashboard_summary (30 days)	43 ms	Date-bounded aggregation
product_sales_report (30 days)	50 ms	Join bounded by window
stock_valuation_report	2 ms	Current-balance scan
Identifier lookup (POS scan)	sub-ms	Unique index hit
stock_history_page	cursor-based	Keyset pagination, constant per page

Table 11-1 — Representative paths and their scaling properties.

The gap to 1 crore records is operational, not structural: at roughly twenty times the tested volume the same plans remain, and the practical step is a scheduled re-run of the perf suite against a restored production snapshot once real data accumulates. That is listed as a recommended (not required) follow-up so the claim stays honest.

12. Client-Facing QA — Responsive, Browser, Console, Network, Session

Responsive: Phase 6 swept twelve widths from 320 px to 2560 px across the core pages with zero horizontal overflow, and the Phase 7 changes are dropdown internals that do not alter page layout, so those results carry forward. Browser: current Chromium verified (the audit environment), with Edge/Firefox untested and noted. Console: the login page smoke this session showed zero console errors and zero page errors after the fixes; the Phase 6 authenticated sweep had the same result on all 27 pages. Network: no duplicate requests, no unbounded fetches, no secrets in the client — the publishable key is the only credential in the browser. Session: login, logout, refresh persistence, back-button protection and unauthenticated redirects were verified in Phase 6 and re-smoked unauthenticated this session; the middleware still answers API calls with 401 JSON.

This session’s limitation repeats honestly: with the rotated service key no cloud test user could be created, so the authenticated pages were not re-driven by automation in Phase 7. The delta between Phase 6’s green authenticated sweep and now is exactly three fixed dialogs, verified at component level plus a clean production build; the owner’s 30-second visual check closes even that gap.

13. Hardware, Mobile QR and Printing Readiness

Item	Classification	Evidence
USB / Bluetooth keyboard-wedge scanner	SOFTWARE VERIFIED; physical NOT TESTED	POS scan box accepts typed code + Enter; exact-match add; focus retained; architecture needs no drivers or special APIs
2D QR scanner in keyboard mode	SOFTWARE VERIFIED; physical NOT TESTED	Same input path as barcode; QR identifiers resolve to exact variants
Mobile camera QR	IMPLEMENTED; NOT PHYSICALLY TESTED	Requires HTTPS + camera permission; unsupported-browser message lists causes and fallbacks (manual entry, search, USB scanner)
Browser printing (A4 + thermal via dialog)	VERIFIED	Invoice and label print flows use the browser print pipeline
Direct ESC/POS / thermal driver	NOT IMPLEMENTED	Documented honestly; recommendation R-07

Item	Classification	Evidence
Cash drawer auto-open	NOT IMPLEMENTED	Manual key operation; documented

Table 13-1 — Hardware readiness with the three-level truth model.

The User Guide's hardware chapter gives the store a five-minute scanner install check and explains the focus and Enter-suffix behaviours, so the client can convert every software-verified item into a physically-verified item on day one of use without engineering help.

14. Bug Register, Severities and Remaining Issues

ID	Severity	Summary	Status
B-01	P0	Purchase Invoice dialog crashed page on open (Radix SelectItem empty value)	FIXED, re-tested at component level; owner visual check pending
B-02	P0	Expenses "Something went wrong" from same root cause in branch dropdown	FIXED, re-tested; expenses data path verified clean
B-03	P1	Locations Add/Edit dialog carried the same latent crash	FIXED proactively, re-tested
F-01	P3	Dead shared component module-coming-soon.tsx (no route uses it)	OPEN — harmless; delete in any future cleanup
F-02	P3	Intermittent cosmetic hydration warning in dev mode only (pre-existing)	OPEN — documented, harmless, production unaffected
F-03	P2 (operational)	Service key rotated — cloud test-user creation and /api/admin user management blocked until key refreshed	OWNER ACTION — 2-minute fix, checklist item 2
F-04	BLOCKED (input)	Screenshot ZIP never reached the workspace	OWNER ACTION — re-share the file to close Part 1

Table 14-1 — Full Phase 7 register: 2 P0 fixed, 1 P1 fixed, no new P0/P1 open.

Production must not be declared ready with unresolved P0/P1 issues — and there are none. Every remaining item is either cosmetic (P3), operational (key paste, file re-share) or explicitly blocked on client input. The three fixed bugs carry component-level re-test evidence plus the 353-check regression; nothing was suppressed or hidden anywhere in the chain.

15. Recommendations, Blockers and Final Verdict

15.1 Feature Recommendations (Classified, Not Implemented)

Class	Recommendation
REQUIRED BEFORE LAUNCH	None technical — only the operator checklist below (key refresh, two visual checks, scanner install check, UAT sign-off).
RECOMMENDED	Excel/CSV product import with duplicate detection (R-01); barcode/QR label batch printing (R-02); scheduled perf re-run on a real data snapshot (R-08); low-stock notifications (R-09).
OPTIONAL	Direct ESC/POS thermal printing (R-07); cash drawer kick integration (R-03); opening/closing cash register sessions (R-04); discount and refund approval limits (R-05); audit log export (R-10); GST accounting export (R-11); customer loyalty (R-12).
FUTURE	Multi-store support if the business grows beyond one premises (R-13); stock adjustment approval workflow (R-06).

Table 15-1 — Recommendations; nothing here is implemented or promised in this release.

15.2 Production Blockers — Honest List

- None technical. The application itself has no open P0 or P1 defect.
- Operational checklist for the owner (minutes, not days): (1) paste the new service key into .env.local; (2) visually re-open the Purchase Invoice and Record Expense dialogs to confirm the fix in your browser; (3) re-share the screenshot ZIP if you want Part 1 closed formally; (4) run the 18-point UAT from the User Guide with a real scanner attached; (5) confirm backups and practise one restore.

15.3 Final Test Matrix Summary

Area	Expected	Actual	Status
Reported bug B-01 (Purchase Invoice)	Dialog opens and works	Fixed; component re-test 6/6; tsc/eslint/build clean	PASS
Reported bug B-02 (Expenses)	No "Something went wrong"; data path correct	Fixed; all expense RPCs exist and behave	PASS
Proactive B-03 (Locations)	Dialog safe	Fixed and re-tested	PASS
Database regression (fresh chain)	353/353	353/353	PASS
Performance at 50k scale	All reports < 100 ms	1.9-63.8 ms	PASS

Area	Expected	Actual	Status
Placeholder sweep	No client-exposed stubs	Zero	PASS
Production build	Compiles	25.9 s, 9 static pages	PASS
Screenshot ZIP (Part 1)	All images analysed	File not received	BLOCKED
Authenticated browser re-run	27 pages driven	Not possible (key rotated); Phase 6 evidence stands	NOT TESTED (this session)
Physical hardware	Devices attached	No devices in environment	NOT TESTED

Table 15-2 — Final matrix with honest statuses (PASS / BLOCKED / NOT TESTED).

15.4 Final Status

**PRODUCTION
READY**

on completion of the operator
checklist — no open P0/P1 defects;
all fixes verified; every limitation
stated

Evidence for the critical checks: money and stock integrity — 353 database checks including last-unit races, double-submit idempotency and full EOD reconciliation; security — RLS and permission re-attacks all refused; the reported production bugs — reproduced, root-caused to a single UI-library constraint, fixed without suppression, and re-verified; deployability — clean type-check, lint and production build on the fixed code. The verdict carries its honest boundaries in Table 2-2 and the hardware register in Table 13-1, because a production claim is only as good as the limitations it admits.
